Restaurant Management System

Description:

A restaurant management system (RMS) is a point of sale (POS) system that can handle fundamental transactions but also supports and benefits you and your employees with other facets of running a restaurant, restaurant booking, marketing, online ordering, loyalty and more.

User Stories to be Developed:

1. As a user, I want to search for restaurants based on seat availability, date, time and cuisine in the application, so that I can book the restaurant (Assume the restaurant data are present).
2. As a user, I want to book seats in a specific restaurant using the application, so that my booking is confirmed.

What?	How?
What are the requirements needs to be the restaurant management system. • User must login the application if the user is new (Register first) • Can search the restaurant based on seat availability • Search based on data, time and cuisine • User can book the restaurant based on above criteria • Now the user can book the seat in particular restaurant • Can confirm your booking	We will build the application using tech stacks on front end: 1. HTML, CSS, Java Script, React it is highly recommendad and very easy to access 2. HTML, CSS, Java Script only without react For the back end we will be using back-end language with framework 1. Java, Spring boot with Rest API using this build structured application. 2. We could use Python
What are the modules will be needed the above requirements • User module • Restaurant module • Search module • Seats availability module • Data and time module • Restaurant details list module	For the data base we will use the data base 1. MySQL data base it is easy to access the data or fetching the data from data base 2. Using Postgres SQL for storing/fetching the data This application we will create with two ways:

For the above modules user credentials could be needed • Username and password • Email address • Contact • Location • Aadhar details	1. Monolithic way of creation 2. Microservices way of creation for better independent performance.
---	---

Why?	Why Not?
We will build the application using tech stacks on front end: 1. HTML, CSS, Java Script, React it is highly recommended and very easy to access Reason: With react we can easily create the component-based application for better reusability For the back end we will be using back-end language with framework 1. Java, Spring boot with Rest API using this build structured application. Reason: Spring boot is a high-level framework in java using it we can easily build logic by annotations. For the data base we will use the data base 1. MySQL data base it is easy to access the data or fetching the data from data base Reason: MySQL data base is very easy to beginner as well as master and also it easy to access data from data base This application we will create with two ways: 1. By using monolithic we can build the application	We will build the application using tech stacks on front end: 1. HTML, CSS, Java Script only without react Reason: Without react we cannot create component based application For the back end we will be using back-end language with framework 1. We could use Python Reason: Python is a high level as well is it is best suitable for like AI projects For the data base we will use the data base 1. Using Postgres SQL for storing/fetching the data Reason: Postgres SQL is very high level as well as the cost effective data base This application we will create with two ways: 1. Microservices way of creation for better independent performance. Reason: Microservices we can use a large application with more services based application.
